You need the following

- Keybase (and access to all the relevant teams)
  - Kedrick uses `brew` a lot. I refuse to pollute my world with that, but YMMV.
  - Since KBFS doesn't work on Monterey, it's likely you'll need to copy files directly from the "Files" section of Keybase
- [Suggested] https://ohmyz.sh/
- https://sdkman.io/ installed and working. Once working (new shell, usually)

```
sdk update
sdk install maven
sdk install java 8.312.07.1-amzn
sdk install java 11.0.13.8.1-amzn
sdk install java 17.0.1.12.1-amzn
sdk install groovy
sdk install gradle
sdk install layrry
```

- https://code.visualstudio.com/
- https://obsidian.md/
- https://www.eclipse.org/downloads/packages/ (Java and DSL developers) is suggested, but not required
  - The developers use whatever IntelliJ-backed golang thing Jetbrains uses, most of the time (I think)
- Docker
- VirtualBox and the addons
- GPG Keychain (for the Mac)
  - You'll want.a published Key for your email address
- `~/.m2/settings-security.xml` with this content (Monterey uses can just copy the file from `rialticsecrets` to `~/.m2`, but you won't get updates if we execute a Rialtic Full Rekey)

```
<settingsSecurity>
<relocation>${env.KBFS_HOME}/team/rialticsecrets/settings-security.xml</relocation>
</settingsSecurity>
```

- `settings.xml` from Keybase/`rialticsecrets`, modified to use your key id and passphrase for GPG

  - This is currently being modified pretty heavily so updates will be frequent

- Terraform 1.0.11 (currently)

- Packer 1.7.8 (currently)

Other tools might become necessary. We'll try to keep this current
